

Python Keywords

Name	Keyword / Syntax	Description
Print Output	<code>print()</code>	Displays output on the screen.
Input	<code>input()</code>	Accepts input from the user.
Variable	<code>x = 10</code>	Stores a value in memory.
Data Type	<code>type()</code>	Returns the data type of a variable.
Integer	<code>int()</code>	Converts a value to an integer.
Float	<code>float()</code>	Converts a value to a floating-point number.
String	<code>str()</code>	Converts a value to a string.
Boolean	<code>bool()</code>	Converts a value to True or False.
List	<code>[]</code>	Stores multiple ordered and mutable values.
Tuple	<code>()</code>	Stores multiple ordered and immutable values.
Set	<code>{}</code> / <code>set()</code>	Stores unique unordered values.
Dictionary	<code>{key: value}</code>	Stores data in key-value pairs.
Length	<code>len()</code>	Returns the number of items.
Range	<code>range()</code>	Generates a sequence of numbers.
If Statement	<code>if</code>	Executes code when a condition is true.
Else Statement	<code>else</code>	Executes code when the condition is false.
Elif Statement	<code>elif</code>	Checks multiple conditions.
For Loop	<code>for</code>	Repeats a block of code for each item.
While Loop	<code>while</code>	Repeats code while a condition is true.

Name	Keyword / Syntax	Description
Break	<code>break</code>	Exits the loop immediately.
Continue	<code>continue</code>	Skips the current iteration of the loop.
Pass	<code>pass</code>	Placeholder that does nothing.
Function	<code>def</code>	Defines a reusable block of code.
Return	<code>return</code>	Sends a value back from a function.
Lambda Function	<code>lambda</code>	Creates a small anonymous function.
Import Module	<code>import</code>	Imports a module or library.
From Import	<code>from ... import</code>	Imports specific items from a module.
Class	<code>class</code>	Defines a blueprint for objects.
Object	<code>obj = ClassName()</code>	Creates an object from a class.
Constructor	<code>__init__()</code>	Initializes object attributes.
Inheritance	<code>class Child(Parent)</code>	Allows one class to inherit another.
Encapsulation	<code>_ / __</code>	Restricts direct access to data.
Polymorphism	<code>Method Overriding</code>	Allows the same method name with different behavior.
Abstraction	<code>ABC,</code> <code>@abstractmethod</code>	Hides implementation details.
Exception Handling	<code>try, except</code>	Handles runtime errors.
Finally Block	<code>finally</code>	Executes code regardless of exceptions.
File Open	<code>open()</code>	Opens a file.
Read File	<code>read()</code>	Reads the contents of a file.
Write File	<code>write()</code>	Writes data to a file.
Append File	<code>append()</code>	Adds data to the end of a file.
Formatted String	<code>f"{}"</code>	Inserts variables into strings.

Name	Keyword / Syntax	Description
List Comprehension	[x for x in ...]	Creates a list in a single line.
Membership Operator	in, not in	Checks whether a value exists.
Identity Operator	is, is not	Compares object identity.
Logical Operators	and, or, not	Combines conditional expressions.
Arithmetic Operators	+, -, *, /, //, %, **	Performs mathematical operations.
Comparison Operators	==, !=, >, <, >=, <=	Compares two values.
